The work described herein was done by The Boeing Company,  
Wichita Division, under NASA contract NAS 3-14321 with Mr.  
H. Bloomer, V/STOL and Noise Division, NASA - Lewis  
Research Center, as Project Manager.

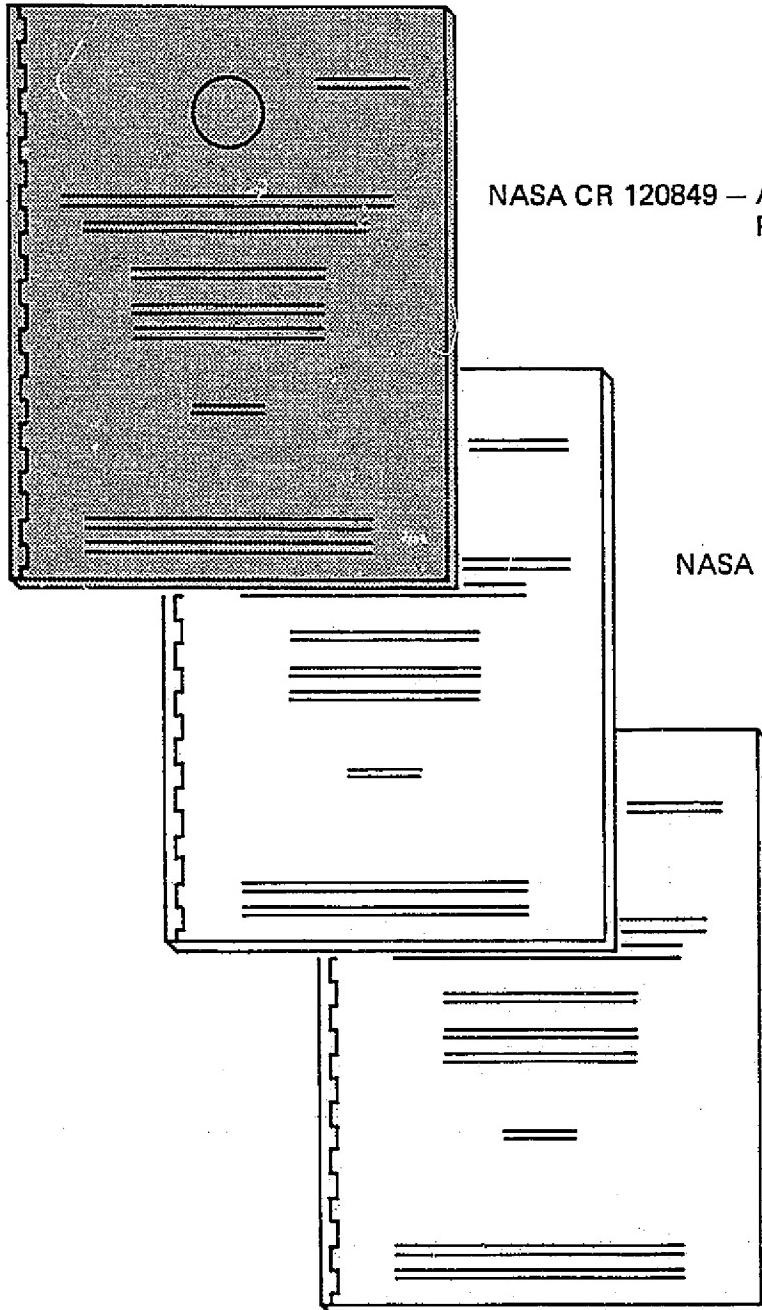

## **ABSTRACT**

An acoustic radiation analysis has been developed to predict the far field characteristics of fan noise radiated from an acoustically lined unflanged duct. This analysis is comprised of three modular digital computer programs which together provide a capability of accounting for the impedance mismatch at the duct exit plane. This report discusses the Acoustic Source Distribution Program whose relationship with the other two modular reports of the analysis is illustrated on the following page.

Admissible duct configurations include circular or annular, with or without an extended centerbody. This variation in duct configurations provides a capability of modeling inlet and fan duct noise radiation.

## 1.0 INTRODUCTION

### 1.1 Background

This report discusses the Acoustic Source Distribution Program which forms the foundation for a package of modular computer programs which together provide a first generation capability for the analytical prediction of the far field noise being radiated from an unflanged inlet or exhaust duct.

The development of these programs has its origin in the need for a method of predicting the far field characteristics of fan or compressor noise radiating from an acoustically treated duct. Among the techniques available in the literature are rigorous solutions for the case of sound radiation from unflanged, hard-walled circular pipes both with and without mean flow (uniform cylindrical jet) published by Levine and Schwinger, Reference 1; and Carrier, Reference 2 (valid only for plane wave propagation in the pipe); solutions for higher duct modes (no flow) by Vajnshtejn, Reference 3; and extensions to References 1, 2, and 3 by Lansing; Drischler and Pusey, Reference 4; where in the closed form solutions for higher duct modes (with flow) have been numerically evaluated. However, these solutions are not applicable to the more complex problems of noise radiated from lined and annular ducts.

A method which can be applied to more general cases is the distributed source technique in which a surface distribution of elementary acoustic sources is determined, by numerical means, such that appropriate boundary conditions are satisfied on the surface. By distributing sources over a circular or an annular aperture in an infinite plane, Morfey, References 5 and 6, and Tyler and Sofrin, Reference 7, were able to predict the acoustic radiation characteristics of flanged ducts. Researchers in underwater acoustics, for example, Chen and Schweikert, Reference 8, have modeled the acoustical radiation properties of a vibrating body of arbitrary shape by using distributions of acoustic sources over the entire outer surface of the body. Martenson and Liu, Reference 9, extended this work to the case of an engine nacelle. By distributing sources over the nacelle walls and the source (fan) plane, they represented both the propagating field in the nacelle and the radiating field exterior to the nacelle, thus, accounting for the diffraction effects at the lip of the nacelle exit plane.

The Acoustic Source Distribution Program described herein is a further extension to these various source distribution methods which builds on the previous work to yield what is felt to be a basically more versatile method of approach. The program utilizes ducts of semi-infinite geometry, from which nacelles may be modeled by coupling of the inlet and exhaust radiation patterns in the far-field, Reference 10. The approach taken is to distribute acoustic sources over the duct walls and the duct exit plane. In this manner, edge diffraction effects are fully taken into account; however, the choice of the source and propagation (interior duct) model to be utilized is fairly arbitrary. The two problems are coupled at the exit plane through consideration of the duct termination impedance, Reference 11.

## 1.2 Technical Approach

The approach taken here involves the application of a numerical technique, the box-integration method, to determine a spatial distribution of acoustic sources over the duct walls and exit plane which satisfies the specified boundary conditions. The conditions imposed are, first, that the acoustic perturbation velocity normal to the rigid outer duct walls vanish, and second, that the velocity distribution over the face of the duct exit plane equals that associated with a given angular mode of sound propagation in the duct.

Admissible duct configurations, shown in Figure 1, include unflanged circular or annular ducts, with or without an extended centerbody. Given the source distribution over the duct, the far-field directivity may be found by numerical integration of the Helmholtz integrals for the velocity potential at large distances from the duct exit plane, Reference 10.

Note that this program assumes knowledge of the actual velocity distribution at the face of the duct. A given duct mode, when incident on the duct exit plane, will generate a reflected wave composed of other duct modes because of the termination impedance mismatch. Thus, the assumption that the velocity distribution at the exit plane is that due to an incident mode generated inside the duct is only a first approximation to the actual radiated noise. The Duct Termination Impedance Program, Reference 11, was written to provide a means for accounting for the impedance mismatch at the duct exit plane.

There are several limitations to this first generation program. First, for the sake of expediency, mean flow within the duct has been neglected. It is anticipated that this simplification will not significantly affect results for noise propagation through a locally subsonic flow field of an inlet. However, radiation through an exhaust or jet flow will undoubtedly not be represented properly by the present model. The second limitation to the program is restriction of the specified velocity distribution on the face of the duct to a  $\cos(m\theta)$  type of angular dependence. Note that coupling of different  $m$  modes in the far-field may still be accomplished by superposition of the source distributions, Reference 10.

The assumption of a  $\cos(m\theta)$  angular dependence does, however, restrict the Duct Termination Impedance Program to the extent that for a velocity distribution whose angular dependence is specified by a combination of different  $m$  angular modes a separate analysis must be made for each set of angular modes. This limitation could be alleviated possibly by employing a collocation procedure in place of the box-method integration technique used in the present program.

The most restrictive limitation to the program at present is one of size and corresponding computer time. As discussed in Section 4.2, the wavelength of the radiated sound affects both the maximum box size used in the program and the required integration distance along the duct wall. To adequately represent the spatial variation of the source strength distribution over the duct there should be at least two boxes per wavelength, (i.e., the box size decreases with increasing frequency). At the same time, however, in order that

the far-field behavior at angles greater than 140 degrees be accurately represented, it is necessary that the integration on the duct outer wall extend back farther as the frequency increases. Together these two requirements indicate that at higher frequencies, a very large number of small boxes are required.

A similar problem involves the requirement for a very high number of angular boxes when attempting to represent the radiation characteristics of rotor-stator interaction modes at high angular mode numbers.

As presently viewed, the primary change required in this first generation program is the need to develop a finite length duct representation. This change is not a simple extension to the present program due to certain inherent mathematical problems, Reference 12, but the basic logic and numerical techniques used presently are directly applicable to the anticipated formulation.

## 2.0 MATHEMATICAL DEVELOPMENT

Figure 2 illustrates the geometry of the problem. The outer duct walls and the duct exit face are each represented by distributions of monopole singularities. Note that the source distributions along the duct walls are required to yield the unflanged duct boundary condition of zero perturbation velocity normal to the outer duct wall. The velocity potential at an arbitrary point in the region outside the duct is given by:

$$\phi(r, \theta, z, t) = \sum_{j=0}^2 \phi_j(r, \theta, z, t) \quad (1)$$

where  $\phi_0$ ,  $\phi_1$ , and  $\phi_2$  represent the contributions of the source distributions over the duct exit plane, the outer duct wall, and the extended centerbody wall, respectively.

Since  $\phi$  must satisfy the wave equation and represent outward propagating waves, it will have the form:

$$\phi(R, t) = \frac{1}{R} \phi(t - R/c)$$

For discrete frequency noise, the velocity potential may then be written:

$$\phi(R, t) = \sum_{j=0}^2 \iint_j \frac{\phi_j e^{i\omega(t-R_j/c)}}{R_j} dS_j \quad (2)$$

where

$$\iint_0 \text{ has limits } a \leq r_0 \leq b, \quad 0 \leq \theta \leq 2\pi$$

$$\iint_1 \text{ has limits } -\infty \leq z_1 \leq 0, \quad 0 \leq \theta \leq 2\pi$$

$$\iint_2 \text{ has limits } 0 \leq z_2 \leq \infty, \quad 0 \leq \theta \leq 2\pi$$

$$R_j = \sqrt{(r \cos \theta - \lambda_j \cos \theta_j)^2 + (r \sin \theta - \lambda_j \sin \theta_j)^2 + (z - z_j)^2}$$

$$\lambda_0 = r_0$$

$$\lambda_1 = b$$

$$\lambda_2 = a$$

$$z_0 = 0$$

PRECEDING PAGE BLANK NOT FILMED

$$dS_0 = r_0 dr_0 d\theta_0$$

$$dS_1 = b d\theta_1 dz_1$$

$$dS_2 = c d\theta_2 dz_2$$

The  $\phi_j$ 's are the unknown source strength distributions.

$$\phi_0 = \Phi_0(r_0, \theta_0)$$

$$\phi_1 = \Phi_1(\theta_1, z_1)$$

$$\phi_2 = \Phi_2(\theta_2, z_2)$$

The boundary conditions to be applied are:

A. Zero normal velocity on the outer duct walls

$$\begin{aligned} U &= -\frac{\partial \phi}{\partial r} = 0 & \left| \begin{array}{l} r=b \\ z \geq 0 \end{array} \right. \\ U &= -\frac{\partial \phi}{\partial r} = 0 & \left| \begin{array}{l} r=a \\ z \geq 0 \end{array} \right. \end{aligned} \quad (3)$$

B. A prescribed velocity distribution over the face of the duct exit:

$$v = -\frac{\partial \phi}{\partial r} = V(r) \cos(m\theta) e^{-i\omega t} \quad \left| \begin{array}{l} z=0 \\ a \leq r \leq b \end{array} \right. \quad (4)$$

Applying Equations (3) and (4) to Equation (2) yields the equations:

$$\sum_{j=0}^2 \iint_j \frac{\phi_j e^{i\omega(t-R_j/c)}}{R_j^3} \left[ 1 - \frac{i\omega R_j}{c} \right] [\alpha_j] dS_j = V(r, \theta, 0) e^{-i\omega t} \quad (5)$$

$$\sum_{j=0}^2 \iint_j \frac{\phi_j e^{-i\omega(t-R_j/c)}}{R_j^3} \left[ 1 - \frac{i\omega R_j}{c} \right] [b - \gamma_j] dS_j = 0 \quad (6)$$

$$\sum_{j=0}^2 \iint_j \frac{\phi_j e^{i\omega(t-R_j/c)}}{R_j^3} \left[ 1 - \frac{i\omega R_j}{c} \right] [a - \gamma_j] dS_j = 0 \quad (7)$$

where

$$\gamma_0 = r_0 \cos(\theta - \theta_0), \quad \alpha_0 = z$$

$$\gamma_1 = b \cos(\theta - \theta_1), \quad \alpha_1 = -z,$$

(8)

$$\gamma_2 = a \cos(\theta - \theta_2), \quad \alpha_2 = -z_2$$

Note that the first integral in Equation (5) vanishes except at its singular point  $R_0 = 0$ . The integral may be evaluated and found to yield the finite contributions over the duct:  $2\pi\Phi_0 @ R_0 = 0; \quad 0 @ R_0 \neq 0$ .

Equations (5), (6), and (7) constitute the integral equations to be used to determine the source strength distributions over the duct.

### 3.0 METHOD OF SOLUTION

The numerical technique chosen to solve Equations (5) through (7) is a "box-integration" method similar to that used in Reference 8. The method involves dividing the surface of the duct into a series of discrete areas and assuming that the source strength distribution over a given area or "box" is constant. The  $\phi_j$  may then be taken out from under the integral sign and the integrals evaluated. By requiring that Equations (5), (6) and (7) be satisfied at a finite number of control points, a set of simultaneous linear algebraic equations are obtained for the unknown  $\phi_j$ .

As the first step in solving the system of integral Equations (5) through (7), the fact that the desired source strength distributions must be single valued in angular dependence is utilized. Knowing the angular dependence of the modal velocity distributions in the duct to be of the form  $\cos(m\theta)$ , the  $\phi_j$  are taken as:

$$\phi_j(r_j, \theta_j, z_j) = \Phi_j(r_j, z_j) \cos(m\theta_j) \quad (9)$$

Thus by specifying the angular dependence of the  $\phi_j$ , the number of control points is vastly reduced since now Equations (5) through (7) need be evaluated at only one angular position.

Next, divide the duct exit face into a series of M annular rings and the duct walls into N and N2 cylindrical segments as depicted in Figure 3.

Considering for the moment only Equation (5), segmentation yields the relation:

$$\begin{aligned}
 & 2\pi\Phi_0(r_0)\cos(m\theta_0)\delta(r-r_0, \theta-\theta_0) \\
 & + \left\{ \int_{z_1=-\infty}^{\xi} \int_{\theta_1=0}^{2\pi} [\text{Integrand}(z_1, \theta_1)] dS_1 + \dots \right. \\
 & \quad \left. + \int_{\xi_N}^0 \int_{\theta_1=0}^{2\pi} [\text{Integrand}(z_1, \theta_1)] dS_1 \right\} \\
 & + \left\{ \int_{z_2=0}^{\eta} \int_{\theta_2=0}^{2\pi} [\text{Integrand}(z_2, \theta_2)] dS_2 + \dots \right. \\
 & \quad \left. + \int_{z_2=\eta_{N2}}^{\infty} \int_{\theta_2=0}^{2\pi} [\text{Integrand}(z_2, \theta_2)] dS_2 \right\} \\
 & = V(r) \cos(m\theta) e^{-i\omega t} \quad (10)
 \end{aligned}$$

where

$$\delta(r-r_0, \theta-\theta_0) = \begin{cases} 0 & \text{if } r \neq r_0 \text{ or } \theta \neq \theta_0 \\ 1 & \text{if } r = r_0 \text{ and } \theta = \theta_0 \end{cases}$$

Physical reasoning implies that

$$\lim_{z \rightarrow \infty} \phi_1(z) = 0 \quad (11)$$

$$\lim_{z \rightarrow \infty} \phi_2(z) = 0$$

since the contribution of the sources on the duct exit plane to the vertical velocity on the duct wall at large distances becomes vanishingly small. This implies then that for practical purposes the integration boxes which extend to infinity may be neglected, that is, the integrations in the  $z$  directions may be truncated. Assume that the  $\Phi_j$  are constant over each of their respective boxes so that:

$$\begin{aligned} & \sum_{I=1}^M 2\pi \phi_0(I) \cos(m\theta_0) \delta(r-r_I, \theta-\theta_0) \\ & + \sum_{J=1}^N \phi_1(J) \int_{\Delta z_J}^{2\pi} \int_{\theta_1=0}^{2\pi} [\text{Integrand}(z_1, \theta_1)] \cos(m\theta_1) dS_1 \\ & + \sum_{J=1}^{N2} \phi_2(J) \int_{\Delta z_J}^{2\pi} \int_{\theta_2=0}^{2\pi} [\text{Integrand}(z_2, \theta_2)] \cos(m\theta_2) dS_2 = V(r) \cos(m\theta) e^{-i\omega t} \end{aligned} \quad (12)$$

For the sake of computational expediency, the control points for Equation (12) and the equivalent forms of Equations (6) and (7), are chosen at  $\theta = 0$ , and at the center of the annular or cylindrical segments. Specifically, Equation (5) is satisfied at  $M$  points on the face of the duct, Equation (6) at  $N$  points on the outer duct wall, and Equation (7) at  $N2$  points on the extended centerbody wall. By this procedure Equations (5), (6), and (7) become:

$$\begin{pmatrix} V \\ 0 \end{pmatrix} = \begin{pmatrix} D & A \\ B & C \end{pmatrix} \begin{pmatrix} \phi_0 \\ \phi_1 \\ \phi_2 \end{pmatrix} \quad (13)$$

where

$[D]$  is an  $M \times M$  diagonal matrix whose elements are  $D_{ii} = 2\pi$ ,  $i = 1, M$ ,

$[A]$  is an  $M \times (N + N2)$  matrix,

$[B]$  is an  $(N + N2) \times M$  matrix,

and

$[C]$  is an  $(N + N2) \times (N + N2)$  matrix.

By expanding the partitioned matrix Equation (13), the unknown  $\phi_j$ 's may be determined as:

$$\begin{Bmatrix} \phi_1 \\ \phi_2 \end{Bmatrix} = - \left[ 2\pi [C] - [B][A]^{-1} [B] \right] \{V\} \quad (14)$$

$$\{\phi_0\} = \frac{1}{2\pi} \{V\} - \frac{1}{2\pi} [A] \begin{Bmatrix} \phi_1 \\ \phi_2 \end{Bmatrix}$$

A note on the method of integration used to obtain the elements of the coefficient matrices A, B, and C in Equation (14) is in order.

First of all, the annular and cylindrical segments of the duct are further subdivided into L angular regions. The integrals are then evaluated over each segment by using an even order Gaussian quadrature scheme. The order of the quadrature is increased by 2 and the integral values compared. If agreement is not obtained, the order is again increased and the procedure repeated until the integral value converges.

During development of the program difficulty in obtaining convergence was noted whenever the integration box was equal to or, in the case of small blocks, closely adjacent to a control box. This is a result of the singular nature of the integrals in Equations (5), (6) and (7) when  $R_j = 0$ , and is of concern since the number of arithmetic operations increases as the square of the order. For this reason, an approximate closed form solution for the integration on the outer duct walls for boxes centered on  $\theta = 0^\circ$  was derived. The procedure is valid only if these boxes have an angular width,  $\Delta\theta$  such that  $\cos(m\Delta\theta) \approx 1$ , thus restricting the size of these boxes. Under this assumption, the closed form value contributed by a control block to its own vertical velocity on the duct outer wall (or centerbody) is:

$$\begin{aligned} \Delta\theta\phi_j &\text{ for } m = 0 \\ \frac{2 \sin\left(\frac{m\Delta\theta}{2}\right)}{m} \phi_j &\text{ for } m > 0 \end{aligned}$$

Also, the contribution of a control block on the outer duct wall (centerbody) to the vertical velocity on another control block on the outer duct wall (centerbody) is found to vanish. Figure 4 shows the allowable variation of  $\Delta\theta$  with angular mode number for control boxes on the duct wall.

The only other integrations which have difficulty in converging are those which determine the contribution of control blocks on the face of the duct, to the vertical velocity at control blocks on the duct walls (and vice versa). This problem of nonconvergence exists only for the control blocks on the face of the duct which are near the intersections of the exit plane and the outer and inner walls. As closed form evaluations for these integrals have not yet been obtained, the only solution here is to allow higher quadrature orders, and to accept the increased computer time required for convergence.

## 4.0 RESULTS

### 4.1 Application

The numerical techniques developed in Section 3 are applied to a discrete frequency radiation problem by the following procedure. First, a mathematical representation of the inlet or exhaust duct is determined by selecting one of the three admissible configurations shown in Figure 1. Next the duct segmentation parameters are selected, (a detailed discussion of the proper selection of box breakdown is given in Appendix 1). Finally, the velocity distribution on the duct exit plane must be specified (hard or soft wall) since the acoustic modes are specified by their velocity distribution. For example, to analyze a duct radiation problem of discrete frequency noise emanating from a lined duct, the soft wall modes and their respective contributions to the radiated sound energy must be determined. Far field directivity patterns are determined for each mode and then combined to yield the total noise signature. In the event both an inlet and fan duct are to be modeled, their respective far field directivity patterns can be calculated and then combined to determine the total noise signature of the nacelle.

Several examples of applying the program to each of the three admissible duct configurations shown in Figure 1 are presented. The resulting source distributions and directivity patterns are used to evaluate the utility and accuracy of the program. For each example problem presented the frequency and outside duct radius were chosen to ensure that only the plane wave mode would propagate down the infinitely long duct. Values of the acoustic and duct segmentation parameters are presented in Table 4.1.

TABLE 4.1  
TABULATION OF ACOUSTIC AND DUCT SEGMENTATION PARAMETERS

PROBLEM	FREQUENCY PARAMETER kb	RADIUS RATIO a/b	SEGMENTATION PARAMETERS			INTEGRATION LIMIT
			EXIT PLANE	OUTER WALL	CENTERBODY WALL	
1	1.0	0.0	16	40	0	4.1
2	1.0	0.5	16	40	0	4.1
3	1.0	0.5	10	10	10	1.375
4	1.0	0.5	10	20	20	2.6

#### Example Problem 1

Noise radiating from a nacelle inlet is represented by a circular duct configuration. The resulting source distributions on the duct exit plane  $\Phi_0$ , and outer duct wall  $\Phi_1$ , are presented in Figures 5 and 9 respectively. To illustrate the behavior of  $\Phi_0$  and  $\Phi_1$ , two

plots of each source distribution are presented. The smaller plot is a duplicate of the large one for an expanded scale. Note the extremely large slope of these distributions near the lip of the duct. This behavior which is due to the discontinuity in the velocity distribution, is discussed in detail in Appendix 1. Aside from the singularity near the duct lip, the behavior of the outer wall source distribution,  $\Phi_1$ , along the duct wall is important. For a proper box breakdown,  $\Phi_1$  should exhibit a strong decay near the duct lip with small amplitude oscillations along the remainder of the duct. A normalized directivity pattern is shown on a polar plot in Figure 15. This pattern is compared with the results obtained by a numerical calculation based on the closed form solution given by Lansing, Reference 4.

#### Example Problem 2

The program was applied to an annular duct configuration to determine the effect of a centerbody on the far field directivity pattern. Source distributions for the duct exit plane and the outer duct wall are presented in Figures 6 and 10 respectively. The discontinuity in the source distribution on the duct exit plane at  $r/b = 0.5$  is due to the discontinuity in the velocity at the inner duct wall. A comparison of the resulting normalized directivity pattern shown in Figure 16 and the normalized pattern of the circular duct shows the effect of the inner duct wall on the far field radiation.

#### Example Problem 3

Noise radiating from a nacelle fan duct is modeled by extending the inner centerbody past the duct exit plane. Source distributions for the duct exit plane, outer duct wall and extended centerbody wall are shown in Figures 7, 11, and 13 respectively. Singularities in the exit plane source distribution occur near the extended centerbody wall as well as near the outer lip of the duct. The extended centerbody source distribution  $\Phi_2$  exhibits several large oscillations before decaying. The effect of the extended centerbody wall on the normalized directivity pattern is shown in Figure 17 to modify the circular duct pattern near the  $90^\circ$  region.

#### Example Problem 4

The annular duct with an extended centerbody is modeled with a different box breakdown than that used in Problem 3. The box breakdown of the extended centerbody wall was refined near the duct exit plane and additional boxes on the centerbody carried the integration farther back on the wall. Source distributions for the duct exit plane, outer duct wall and extended centerbody wall are shown in Figures 8, 12 and 14. The directivity pattern of Figure 18 shows the effect of modifying the box breakdown on the duct. Finer breakdown yields a pattern that is closer to circular duct pattern than was observed in the coarse breakdown of Example Problem 3.

#### 4.2 Limitations

There are several limitations to this program. First, mean flow within the duct has been neglected. Although application of this analysis to a nacelle radiation problem does not yield an exact model, it is anticipated that this simplification will not significantly affect

results for noise propagation through a locally subsonic flow field of an inlet. However, radiation through an exhaust or jet flow will not be represented properly by the present analysis.

The second limitation to the program is restriction of the specified velocity distribution on the face of the duct to a  $\cos(m\theta)$  type of angular dependence. This assumption does not affect the capability of the program to combine different  $m$  angular modes in the far field by superposition of the source distributions, Reference 10. It does, however, restrict the Duct Termination Impedance Program, Reference 11 to the extent that for a velocity distribution whose angular dependence is specified by a combination of different  $m$  angular modes a separate analysis must be made for each set of angular modes.

The most restrictive limitation to the program at present is one of required storage size and corresponding computer time. Both of these digital computer usage parameters are related to the wavelength of the radiated sound waves. To adequately represent the spatial variation of the source strength distribution over the duct, there should be at least two boxes per wavelength (6 boxes per wavelength is more desirable). In order that the far-field behavior at angles greater than 140 degrees be adequately represented, it is necessary that the integration on the duct outer wall extend back farther as frequency increases. Together these two requirements indicate that at higher frequencies, a very large number of small boxes are required.

Time and storage requirements depend on the number of integrations required to fill the influence matrix in Equation (13). The number of integrations varies with the square of the number of boxes and computer run time is dependent on the number of integrations. When convergence of the numerical quadratures becomes a problem the program requires a considerably larger amount of time to compute the matrix elements. Core storage required by the computer is equal to twice the square of total number of boxes, since the matrix elements are complex numbers. The number of boxes required on the exit plane of the duct becomes critical when radiation patterns of high radial modes are desired. At least two boxes per zero crossing of the velocity distribution is required, (i.e. the 6th radial mode requires at least 12 boxes. A similar problem involves the requirement for a very high number of angular boxes when applying the program to the problem of high angular modes. This requirement increases the computer run time since the number of numerical quadratures is greater.

## 5.0 CONCLUSIONS AND RECOMMENDATIONS

An acoustic radiation analysis has been developed that predicts the angular distribution of acoustic energy in the far field that is radiated from an unflanged duct. This analysis represents a rather unique analytical tool in that it can be applied to hard wall ducts (unlined) with an annular cross-section as well as circular. Both circular and annular duct configurations with their interior walls lined with noise suppression material can be analyzed. For all duct configurations with either hard or soft walls, the far field radiation patterns are corrected for the impedance mismatch at the duct exit plane. Also, of primary importance is the fact that the present analysis permits combination of inlet and exhaust radiation patterns in the far-field.

In spite of its many advantages, this acoustic radiation analysis is limited in its range of application. For this reason, this analysis has been relegated to the role of a first generation analysis in a commitment to develop an analytical package which will predict radiation characteristics of a turbofan jet engine. The present version of the analysis reaches optimum efficiency when it is applied to low frequency noise radiating from an infinite duct. This and other limitations due to a  $\cos(m\theta)$  type of angular dependence of the velocity distribution and the required storage size and corresponding computer time are an inherent property of the "box method" numerical technique.

A second generation version of the program could avoid these limitations by utilizing a collocation technique of evaluating the integrals. The primary feature of this technique is that a selected analytical expression is used to represent the source distribution. The time saving feature of the collocation technique is that it requires fewer evaluations of the integrals. The collocation procedure would enable the analysis to handle any combination of angular modes, a result which would remove the angular modal coupling limitation for the Impedance Program, Reference 11, and eliminate the need for a large number of angular boxes.

In addition to the collocation procedure, a second generation version of the analysis should contain a method of accounting for a mean flow within the duct. This method should account for the effects of velocity gradients on the distortion of the radiation field by the jet.

A further refinement in the overall development of an analysis to predict turbofan noise would be the incorporation of a finite length duct representation. This change is not a simple extension to the present program due to certain inherent mathematical problems that involve the nonexistence of solutions of the integral equation formulation. As discussed in Reference 12, these problems can be avoided by using an alternate formulation.

A finite duct length representation would require additional analytical considerations. The presence of higher radial modes generated at the duct termination and reflected back toward the source could not be ignored. Their reaction with the noise source and subsequent propagation down the duct towards the exit plane requires that the problem must be analyzed by a systems analysis approach.

## NOMENCLATURE

### Computer Program Variables

A	Centerbody Radius
AA(I,J)	Matrix
B	Outer Duct Radius
BB(I,J)	Matrix
C(I)	Dimensionless Size of Ith Box on Duct Outer Wall
C2(I)	Dimensionless Size of Ith Box on Extended Centerbody Wall
CHK	Convergence Criterion
DD(I,J)	Matrix
D(I)	Dimensionless Size of Ith Box on Duct Exit Face
INK	Configuration Parameter
IV	No. of Velocity Distributions to be Read In
K	No. of Polar Angles at which Far Field Data is Required
L	No. of Angular Boxes
MW	Angular Mode No.
M	No. of Annular Boxes
N	No. of Cylindrical Boxes on Duct Wall
N2	No. of Cylindrical Boxes on Extended Centerbody Wall
NNZ	No. of Velocities to be Computed by VELINT
PHI(I)	Source Strength Distribution
R	Radial Coordinate
RO,RI	Distance Between Point on Duct and Field Point
S	Sound Speed in Air
TT	Angular Coordinate
TI	Angular Coordinate Integration Variable
V(I)	Velocity Distribution on Exit Face
W	Frequency Radians/Second
WDS	Wavenumber W/S
XANG	Nondimensional Angular Size for Control Box
ZZ	Axial Coordinate

## INPUT DATA

Since the accuracy of the source strength distribution obtained from this program is critically dependent on the method of segmentation of the duct walls and exit face, a brief discussion of the pertinent points is in order. In addition to the requirements that the control boxes have a small angular width such that  $\text{Cos}(m\Delta\theta) \approx 1.0$  and that there be two or more boxes per wavelength of the radiated sound, there are restrictions on the size of the annular and cylindrical segment heights ( $\Delta r$  and  $\Delta z$ , respectively) in the region of the intersection of the duct walls and the exit plane. This requirement must be satisfied, primarily, to accurately compute the near field pressure (over the duct exit face).

The discontinuous velocity along this intersection results in the  $\phi_j$ 's being singular there. (An inner asymptotic expansion of the wave equation near the intersection has revealed that the singularity is one in slope of the  $\phi_j$  versus  $z$  or  $r$  curves. Specifically, as the intersection is approached, the  $\phi_j$  behave as  $|x| \ln|x|$ ,  $x$  going to zero, where  $\ln$  denotes the natural logarithm.)

Adequate representation of this singular behaviour requires a fine breakdown in the region of the intersection. For a duct of radius  $b$ , the breakdown near the intersection should consist of several boxes ranging in size from  $0.01b$  up to  $0.05b$ . For all duct configurations the fine breakdown would be necessary near the duct lip on both the face and the wall. For an annular duct it is also necessary on the face on both sides of the inner annulus wall, whereas for the annular duct with an extended centerbody, the fine segmentation is necessary on the face and centerbody wall near their intersection.

As a final note, the box sizes on the face in both the radial and angular directions must naturally decrease in size when higher order modes with many modal lines are represented.

CARD OR CARD SET	FORMAT	DATA
1	18A4	Title of run
2	NAMELIST	Logical Parameters: PUNCH = T(F) yields (does not yield) punched card output to be used in the directivity index program.  OLD = T(F) bypasses (does not bypass) the integration loops and uses (does not use) previously generated matrices in the MATX program to compute PHI distributions for new velocities. Delete card (sets) 3 through 7 if OLD = T.
3	30I2	Integer Parameters: L = No. of Angular Segements M = No. of Annular Segments N = No. of Cylindrical Segments NN = Order of Initial Gauss Quadrature (NN Even) LP = No. of Integrations in Integration Routine MW = Angular Mode Number INK = Configuration Parameter (0 - Circular or Annular Duct, 1 - Annular Duct with Extended Centerbody)

K = No. of Angles at which Far Field Pressure Values are to be computed.

N2 = No. of Cylindrical Segments on Centerbody.

4	7F10.3	A = Centerbody Radius (A = 0.0 for Circular or Annular Ducts) B = Outer Radius of Main Duct W = Frequency, Radians/Second S = Sound Speed in Units Consistent with those of A & B CHK = Convergence Criterion for Numerical Integration XANG - Nondimensional Angular Size for Control Box $\Delta\theta$ Radians = $2\pi$ (XANG) (See Figure 4).
5 (Card Set- N Values, 7 Per Card)	7F10.3	C(I), I = 1, N, the size of the cylindrical segments on the Main Duct Wall in the Z direction, nondimensionalized with respect to B, Numbered with C(1) closest to the duct exit plane and I increasing in the negative Z direction.
6 (Card Set- N2 Values, 7 Per Card)	7F10.3	C2(I), I = 1, N2 <u>Input this set only if INK = 1.</u> Size of cylindrical segments on centerbody wall in Z direction, nondimensionalized with respect to B, numbered with C2(1) closest to the duct exit plane and I increasing in the positive Z direction.
7 (Card Set- M Values, 7 Per Card)	7F10.3	D(I), I = 1, M, the size of the annular segments on the duct exit plane in the radial direction, nondimensionalized with respect to B, Numbered D (1) at the duct centerline (or adjacent to the centerbody wall-duct exit plane intersection) and increasing to D(M) at the lip of the duct.
8	2I2	IV IV 0, IV = No. of velocity distributions to be read from cards. IV = 0, velocity distributions to be computed as hard-wall modal distributions from VELINT.
9 (Card Set- M Complex No's. 3 Per Card)	6E12.5	V(I), I = 1, M, Velocity* distribution on face of duct V(K) = velocity corresponding to segment D(K). - <u>Input this card set only if IV&gt;0.</u>
10	3612	NNZ - No. of Velocity Distribution to be computed by VELINT. <u>Input Card 10 only if IV = 0.</u>

\*NOTE: For annular duct without extended centerbody, the velocity for the boxes on the inner annular area must be set equal to zero.

## PROGRAM FLOW

Flow charts for the box method program and associated subroutines are given in Appendix 2.

The main program consists of the calling program and subroutines CAL200, CAL300 and CAL700. Here the input data are read in and the box method integrations performed. Upon completion of the integration, subroutine MATX is called. This subroutine carries out the matrix manipulations required to solve for the source strength distributions.

Subroutine GAUSS is used in the integration and consists of tables of Gaussian weights and abscissas. Subroutine INVT performs the inversion of complex matrices. Subroutine VELINT is an optional routine which computes modal velocity distributions for hard walled annular ducts. Thus, the velocity distributions may be input directly or computed by VELINT.

## OUTPUT

Output quantities consist of the following:

- A. Input data printout
- B. Results of the integration program, consisting of the contribution of each box to the vertical velocity at each control point.
- C. Results of the matrix operations during which the  $\phi_j$ 's are computed. (Optional)
- D. The values of the source strengths at each box.

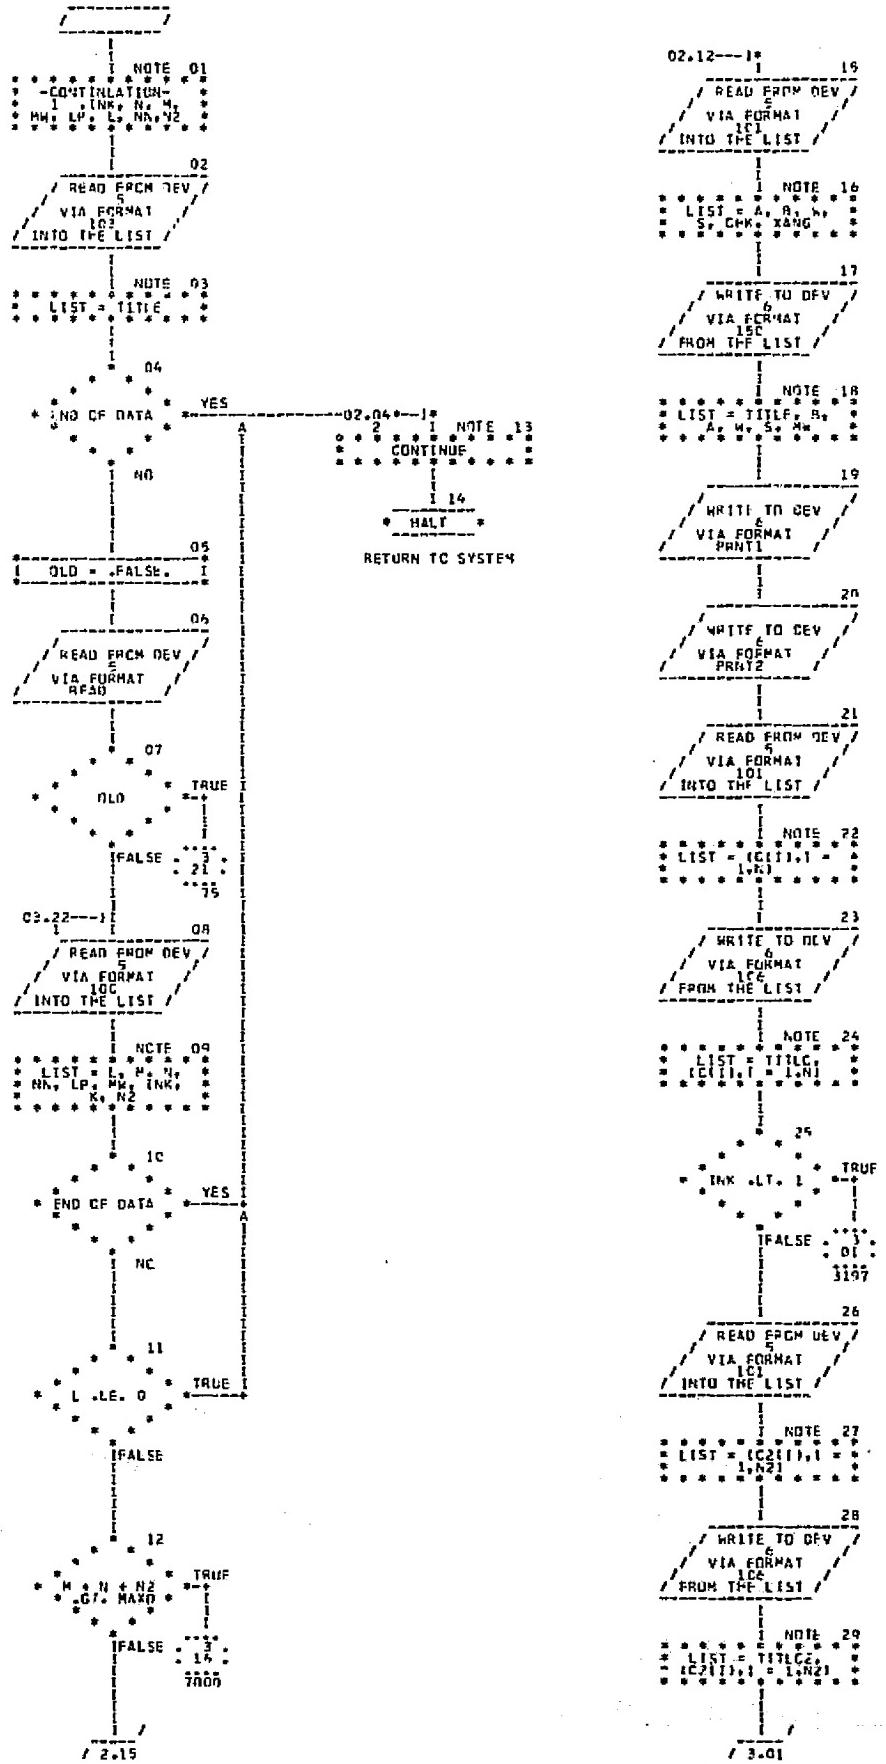

## EXAMPLE PROBLEMS

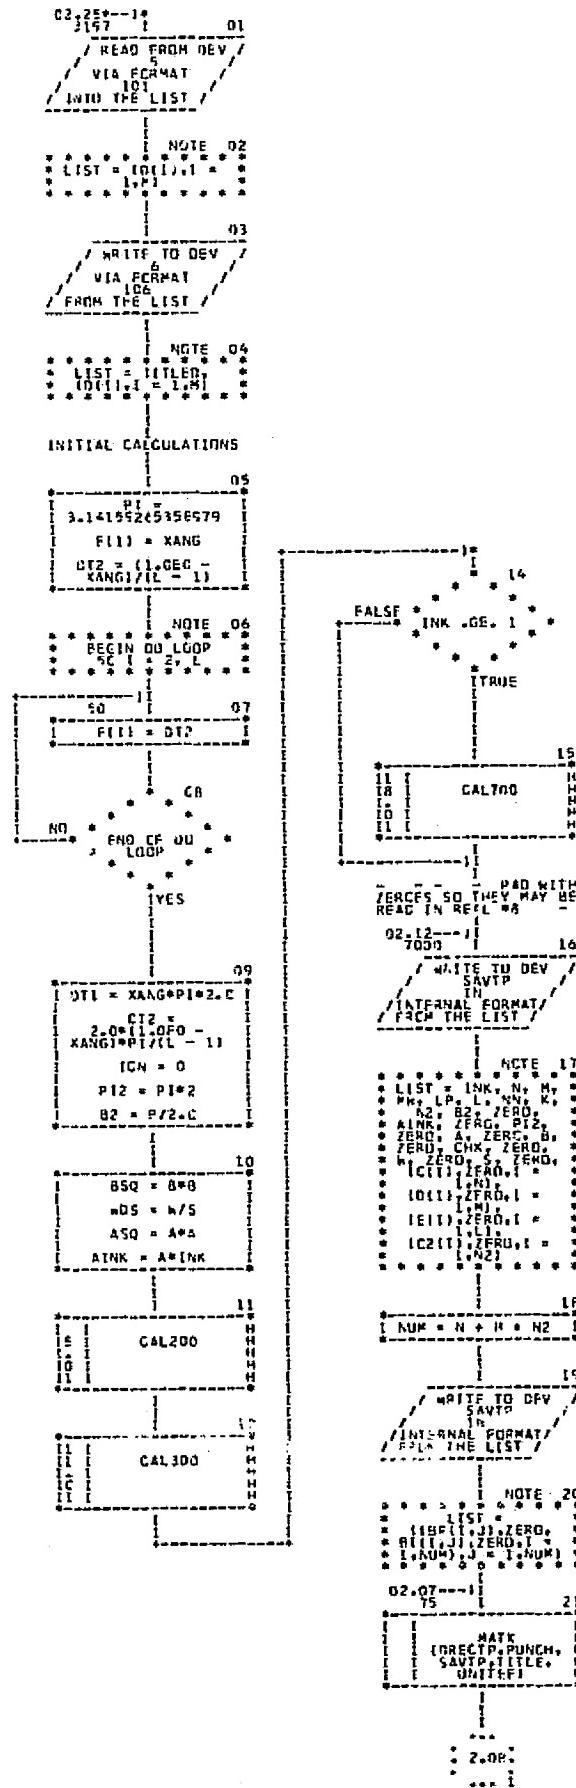

Appendix 8 illustrates the input preparation and output format of the program. A listing of the input data are given for each example problem discussed in Section 4.1. Complete printout (with the exception of the operations performed by MATX) is shown for example Problem 1.
